Project Proposal

Proposal #1: AI-Based Medical Diagnosis System

Many people struggle to get quick medical advice due to time, money, or lack of access to doctors. This AI-based system will help by allowing users to enter symptoms in simple language. It will ask relevant follow-up questions, analyze medical history, and predict possible diseases while offering basic recommendations. The system will feature a symptom input module for easy data entry, a smart questioning system that asks follow-up questions based on user responses, and a medical history analysis to improve accuracy. Additionally, it will provide AI-based diagnosis, health recommendations, and a user-friendly interface supporting text. This tool aims to provide preliminary guidance, reduce unnecessary doctor visits, and help users make informed health decisions. While not a replacement for medical professionals, it will serve as a convenient first step before seeking professional care.

Proposal #2: AI-Based Resume Screening System

Hiring the right candidate is time-consuming and challenging, with recruiters often overwhelmed by large volumes of resumes. This AI-based resume screening system will automate the initial selection process by analyzing resumes, identifying key qualifications, and flagging discrepancies. The system will assess candidate eligibility based on experience, skills, and job requirements, categorizing applications as accepted, flagged for review, or rejected. Features include keyword-based matching, experience and qualification validation, fraud detection, and ranking candidates based on relevance. This tool will streamline recruitment, reduce human bias, and ensure efficient hiring decisions.
